# Introduction

**Retrieval Augmented Generation** is a methodology by which a generative model (e.g. transformer-based neural network) is augmented with external knowledge retrieval. This helps address limitations in LLMs including factual accuracy, timeliness, and access to non-public knowledge.

External knowledge source could involve

- web search
- access to documents / databases / knowledge graphs
- web services

### **Retrieval augmentation**

**Institute of Data Science** 

### Features

- self-hosted/managed
- ranking algorithms
- metadata filtering
- indexing
- access control
- security/privacy certification (SOC, HIPPA, GDPR)

# Methodology

- The query encoder processes the input query to generate a representation suitable for retrieval.
- The retriever uses this representation to fetch relevant documents or data from the database.
- The document database is a pre-compiled collection of texts or knowledge that the retriever queries.
- The generator then takes the original query along with the retrieved documents to generate a coherent and contextually enriched response.

## **Frameworks**

- <u>LangChain</u> (<u>RAG</u>)
- Microsoft <u>Semantic kernel</u>
- <u>LlamaIndex (RAG, notebook)</u>
- <u>llmware</u>

### **LLM provisioning**

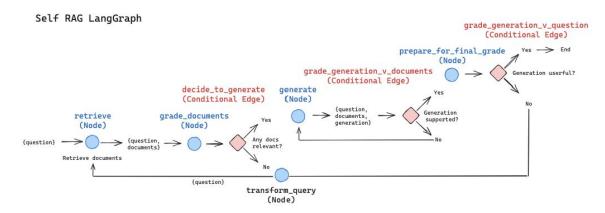

- Ollama download models and serve them up via http
- LlamaCpp
- vLLM

# **Langgraph**

<u>LangGraph</u> is a library for building stateful, multi-actor applications with LLMs, built on top of (and intended to be used with) <u>LangChain</u>. It extends the <u>LangChain Expression Language</u> with the ability to coordinate multiple chains (or actors) across multiple steps of computation in a cyclic manner. <a href="https://github.com/langchain-ai/langgraph">https://github.com/langchain-ai/langgraph</a>

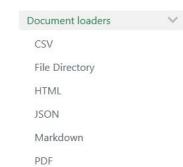

The main use is for adding **cycles** to your LLM application. Crucially, this is NOT a **DAG** framework. If you want to build a DAG, you should just use <u>LangChain Expression Language</u>.

Cycles are important for agent-like behaviors, where you call an LLM in a loop, asking it what action to take next.

# **Document loaders**

First step is to load a collection of documents for processing. Many integrations available.

# Maastricht University Institute of Data Science

# **Text Splitting**

We will need to split the documents into chunks that facilitate the retrieval of a sufficiently large context to help answer the question but can also fit into the llm context window.

### Split by:

- # of tokens, character, sentence, paragraph
- document structure (e.g. HTML headers)
- semantic structure
- multi-vector indexing

see notebook

**Institute of Data Science** 

Splitter: Character Splitter & Chunk Size: 35
Chunk Overlap: 4
Total Characters: 91
Number of chunks: 3
Average chunk size: 30.3

This is the text I would like to chunk up. It is the example text for this exercise
Chunk #1
Overlap
Chunk #2
Overlap Chunk #3

One of the most important things I didn't understand about the world when I was a child is the degree to which the returns for performance are superlinear.

Teachers and coaches implicitly told us the returns were linear. "You get out," I heard a thousand times, "what you put in." They meant well, but this is rarely true. If your product is only half as good as your competitor's, you don't get half as many customers. You get no customers, and you go out of business.

It's obviously true that the returns for performance are superlinear in business. Some think this is a flaw of capitalism, and that if we changed the rules it would stop being true. But superlinear returns for performance are a feature of the world, not an artifact of rules we've invented. We see the same pattern in fame, power, military victories, knowledge, and even benefit to humanity. In all of these, the rich get richer. [1]

Splitter: Character Splitter & 🗸 🗸 Value of the Chunk Size: 25 Significant of the Chunk Overlap: 0 S

Upload .txt

Total Characters: 2658 Number of chunks: 107 Average chunk size: 24.8

One of the most important things I didn't understand about the world when I was a child is the degree to which the returns for performance are superlinear.

Teachers and coaches implicitly told us the returns were linear. "You get out," I heard a thousand times, "what you put in." They meant well, but this is rarely true. If your product is only half as good as your competitor's, you don't get half as many customers. You get no customers, and you go out of business.

It's obviously true that the returns for performance are superlinear in business. Some think this is a flaw of capitalism, and that if we changed the rules it would stop being true. But superlinear returns for performance are a feature of the world, not an artifact of rules we've invented. We see the same pattern in fame, power, milliary victories, knowledge, and even benefit to humanity. In all of these, the rich get richer. [1]

You can't understand the world without understanding the concept of superlinear returns. And if you're ambitious you definitely should, because this will be the wave you surf on.

It may seem as if there are a lot of different situations with superlinear returns, but as far as I can tell they reduce to two fundamental causes: exponential growth and thresholds.

The most obvious case of superlinear returns is when you're working on something that grows exponentially. For example, growing bacterial cultures. When they grow at all, they grow exponentially. But they're tricky to grow. Which means the difference in outcome between someone who's adept at it and someone who's not is very great.

Startups can also grow exponentially, and we see the same pattern there. Some manage to achieve high growth rates. Most don't. And as a result you get qualitatively different outcomes: the companies with high growth rates tend to become immensely valuable, while the ones with lower growth rates may not even survive.

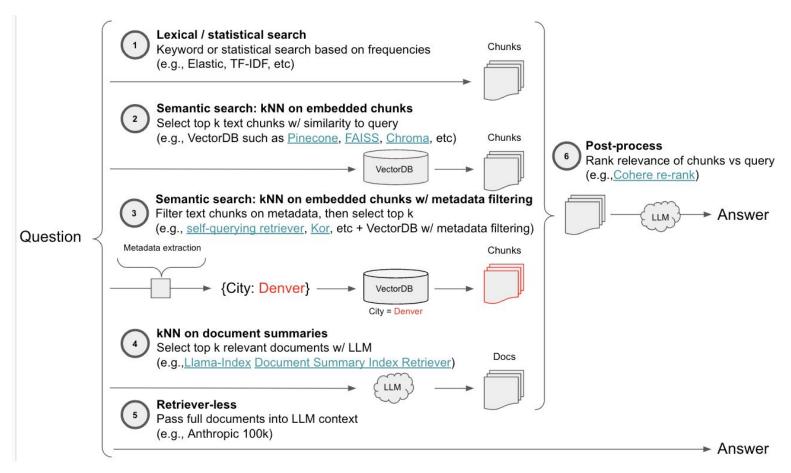

Y Combinator encourages founders to focus on growth rate rather than absolute numbers. It prevents them from being discouraged early on, when the absolute numbers are still low. It also helps them decide what to focus on: you can use growth rate as a compass to tell you how to evolve the company. But the main advantage is that by focusing on growth rate you tend to get something that grows exponentially.

YC doesn't explicitly tell founders that with growth rate "you get out what you put in," but it's not far from the truth. And if growth rate were proportional to performance, then the reward for performance p over time t would be proportional to pt.

Even after decades of thinking about this, I find that sentence startling.

          chunk id: "11c9b"

☐ propositions

             0: "I heard a thousand times that 'You get out what you put in."
             ■ 1: "The statement that 'You get out what you put in' is rarely true."
             2: "You get no customers if your product is only half as good as your competitor's product."
          summary: "This chunk explores the principles of effort and reward, and critiques the saying 'You get out what you put in."
```

# **Multi-vector Indexing**

semantic search for a vector that is derived from something other than the raw text

### summary

use LLM to generate a summary of the full document, which can be indexed for retrieval.

"The document discusses the concept of superlinear returns for performance, where the rewards for performance are not proportional to the effort put in. It explains that this concept is present in various aspects of life, such as business, fame, power, military victories, and benefit to humanity....

### Maastricht University

Institute of Data Science

### hypothetical questions

use LLM to generate hypothetical questions that would best match the document.

["What was the author's first experience with programming like?", 'Why did the author switch their focus from AI to Lisp during their graduate studies?'. 'What led the author to contemplate a

career in art instead of computer

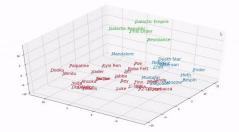

science?']

### parent document

do search against smaller document fragments, and retrieve the parent document section for fuller context

# **Text Embedding □** →

The next step is to embed the text. Use sentence and document embedding models.

<u>Sentence Transformers library</u> is a Python framework for sentence, text and image embeddings. Gives you access to embedding models on hugging face.

<u>"sentence-transformers/all-MiniLM-L6-v2"</u> maps sentences & paragraphs to a 384 dimensional dense vector space and can be used for tasks like clustering or semantic search. It is very small (0.09GB), currently #75 on leaderboard

bge-small-en-v1.5 (0.13GB) currently #29, supported in <u>FastEmbed python</u> library.

# **Summary**

Retrieval Augmented Generation (RAG) is a powerful technique that uses external knowledge sources to augment the capabilities of a Large-Large Model. There are many factors to consider in the development of the pipeline including

- document chunking strategies
- embedding model selection
- vector database selection
- relevancy and corrective techniques

KGs can also be embedded into vectorDBs, with strategies needed to retrieve fragments across the graph span.
